JOB MARKET PAPER      **Of Fathers and Farms: How Intergenerational Persistence Shapes Structural Transformation**

**Abstract.** How does intergenerational persistence in sector choice reshape the dynamics of structural transformation? To study this question, I develop a two-sector general equilibrium Roy model in which workers are either more productive or otherwise more attached to their parents' sectors. Both mechanisms dampen new workers' aggregate responsiveness to relative wages. Across generations, inherited productivity can reverse past reallocation, whereas inherited immobility propagates it. Taking the model to linked father–son records in U.S. historical census microdata, I find that both mechanisms are quantitatively important sources of persistence. In a counterfactual calibrated to U.S. industrialization from 1880 to 1940, eliminating persistence increases reallocation out of agriculture by 14.3 percent of the observed decline. Inherited productivity accounts for nearly all of this effect. Abstracting from intergenerational persistence, the model can reproduce the same observed transition, but infers substantially more growth in nonagricultural relative to agricultural technology.
