JOB MARKET PAPER **Of Fathers and Farms: How Intergenerational Persistence Shapes Structural Transformation**

***Abstract.** New workers drive structural transformation, yet also remain strongly drawn to their parents' sectors. To study how these intergenerational connections shape worker reallocation, I introduce inherited sector-specific productivity and an inherited immobility wedge for farmers' sons into a two-sector Roy model. Viewed through the lens of the model, linked father-son census records from the early 20th century United States imply that workers are 42–81 percent more productive in their parents' sector and that farmers' sons sort as if they are paid 40 percent less for nonagricultural work than equally skilled nonfarmers' sons. Both mechanisms dampen workers' contemporaneous responses to changing labor demand, but inherited productivity can reverse past reallocation in future generations while inherited immobility reinforces it. Calibrating the model to the U.S. transition out of agriculture from 1880 to 1940, I find that eliminating intergenerational persistence increases worker reallocation by 5.1 percentage points, or 13.3 percent of the observed decline in agricultural employment. Inherited productivity explains nearly all of this effect because its contemporaneous and intergenerational effects reinforce each other, whereas those of inherited immobility offset.*
